

PROCESSES AND PROPERTIES OF IRON

The thermomechanical working of white cast iron. Ya. S. Ginzburg and S. I. Kravitskiy, *Soviet Met. Rev.*, No. 1, 1967, 73 (1968); *Chem. Zvest.*, 1967, 1, 900. Forging studies are reported on white cast iron of varying composition. The specimens contained 1.5-10% Cr and 2.6-3.5% C. The forging began at about 1050° and ended at about 850°. With careful working and control of temperature, ingots can be forged without the appearance of internal or external cracks. To date, the best heat treatment for lath tools of wrought white cast iron with 3.35% C; the specimens were quenched in water or oil from 760-1100° and annealed at 1.50°. Structure and Rockwell hardness were determined. The test results (hardness and cutting edge) were obtained by quenching in oil from 850°. M. G. Moore

The Production of Rolled Alloy Steel in Russia at the Twentieth Anniversary of the Revolution. Ya. S. Gintsburg. (Kachestvennaya Stal, 1937, No. 11, pp. 20-26). (In Russian). The author reviews the development of the rolling of alloy steels in Russia. Stages in the development of alloy steels and rolling-mill design are described and special developments such as the production of Nichrome, iron-chromium-aluminum alloys, transformer steel and high-speed steel, as well as work on ingotless rolling, are mentioned.

The Influence of the Austenite Grain Size on the Mechanical Properties of Medium-Carbon Structural Steel. Ya. S. Gintaburg and Ya. B. Shtuchkov. (Kachestvennaya Stal, 1938, No. 2, pp. 23-25). (in Russian). Statistical methods were applied to the study of 122 heats of steel containing carbon 0.30-0.35%, manganese 0.5-0.7%, silicon 0.2-0.3%, sulphur and phosphorus each $\leq 0.04\%$, chromium $\leq 0.2\%$ and nickel $\leq 0.5\%$ with McQuaid-Ehn grain size numbers of 1 to 5. The specimens were taken from rolled sheets and, after normalising and tempering, their tensile properties, impact strength and hardness were determined. The results are presented in the form of curves showing the relationships between the grain size and the above mechanical properties.

ASB 15A METALLURGICAL LITERATURE CLASSIFICATION

Manganese steel as a material for boiler construction. Ya. S. Ginzburg, K. A. Polzelenko and M. S. Freidl. *Khimiya Nal* 6, No. 2, 9-14 (1938); *Chem. Zvesti* 1939, 1, 1031. — The mech. properties at normal and elevated temps., the tendency to age, the resistance to creep stress and the brittleness when hot were tested for Mn steels contg. C 0.23-0.29, Mn 1.3-1.5 and Si 0.25-0.35%. As regards the mech. properties at normal and elevated temps. Mn steel was shown to be a satisfactory steel for boiler construction. While the sensitivity to aging was less than that shown by pure C steels, it was greater than that of age-resistant Al boiler steels, such as Izett steel and Cuprizett steel. It is hoped that by proper methods of smelting the resistance of Mn steels to aging can be improved. M. G. Moore

Text Data

Coverage: In this monograph the prevalent modern methods of mechanical testing the properties and quality of metals at temperatures up to 600°C are dealt with in detail. Because of the wide use of high-pressure steam equipment (boilers, turbines, etc.) in postwar USSR, machine parts are now under higher strain. Special attention is given to the effects of creep, fatigue and relaxation. A short survey of corrosion testing procedures is included.

Evaluation B-84718, 3 Jan 55

AID 444 - I

Ispytaniya metallov pri povyshennykh temperaturakh

Soviet methods and testing machines are discussed at length: e.g., the Brinell hardness test developed by I. L. Mirkin and D. E. Livshits, and the original device of N. T. Gudtsov and M. G. Lozinskiy for determining the aging of metals by the hardness test. This device, according to the author, excels all foreign installations (pp. 50-54, with illustrations). Various testing machines and furnaces of the Central Institute for Boilers and Turbines (TsKTI), of the Central Scientific-Research Institute of Technology and Machine Building (TsNIITMASH) and of many others are fully described.

The book is provided with illustrations, drafts, tables and diagrams.

Title : Some instances of conformity to law in the second period in the testing of austenite steel for relaxation

Periodical : Vest. mash. 34/3, 46-49, Mar/1954

Abstract : The process of relaxation goes on under conditions of uninterrupted softening of the material with a gradual slowing down of speed in accordance with a definite formula. The materials involved in the experiments are principally austenite steel but also carbide type like perlitic, austenitic and austenitic-ferrite compounds. The processes of aging are studied in experiments. Two Russian references, latest 1950. Tables; graphs.

Title : Simplification of Relaxation Tests of Metals and Alloys.

Orig Pub : Zavod. laboratoriya, 1956, 22, No 7, 840-845

Abstract : Within the limits of the second period up to the critical relaxation temperature, the stress-relaxation curves at constant temperature, plotted in coordinates of the initial stress (σ_0) and the stress after prolonged relaxation t (σ_t), is in the shape of a straightline passing through the origin; the slope of the curve depends on t . When plotted in coordinates $\log \sigma_0$ -- $\log \sigma_t$, the above dependence is also linear (subject to the same limitations). Expressing these relations analytically, the author obtains linear equations with empirical coefficients,

Abs Jour : Ref Zhur - Fizika, No. 5, 1957 No. 11696

Abstract : at 650 -- 800° up to 4000 hours. An investigation was made of the change in the magnetic susceptibility of the steels during soaking, the change of the lattice period of austenite, and of the special carbides. It was found that in the study of the processes that take place in paramagnetic steels (aging with decomposition of the austenite and formation of ferromagnetic phases), the magnetic method is more sensitive than the X-ray structural method. In the investigation of ferromagnetic steels, the X-ray structural analysis is more sensitive than the magnetic one.

Chief Ed. of the Leningrad Branch of Mashgiz: Bol'shakov, S.A., Engineer

PURPOSE: This book is intended for engineers in plant laboratories, designers, and scientific personnel in research institutes.

COVERAGE: This book deals with relaxation of stresses in metals. The author discusses the formal and physical theories of stress relaxation and the basic factors of this phenomenon. A description is given of the methods of investigation, the processing and utilization of the results of testing metals for stress relaxation. Methods for increasing relaxation stability of metals are also described. The interrelation between creep and stress relaxation in metals is treated briefly.

AUTHOR: Gintsburg, Ya. S. SOV/32-24-7-36 '65

TITLE: An Apparatus for the Investigation of the Relaxation of the Torsion Stress in Metals (Mashina dlya issledovaniya relaksatsii napryazheniy v metallakh pri kruchenii)

PERIODICAL: Zavodskaya Laboratoriya, 1958, Vol. 24, Nr 7, pp. 865 - 867 (USSR)

ABSTRACT: The compensation method for the investigation of the relaxation of the stretching stress in metals has hitherto not been employed often as it is difficult to carry out a precise reduction of the load in order to obtain the true relaxation curve. In order to achieve this another sort of the stress state of the sample must be chosen; then a greater deformation takes place, which may be obtained with torsion. In connection with this problem torsion tests were carried out with one of the first Soviet machines for creep tests, with cylindrical springs being used in the place of the cylindrical or tubular samples. A.A. Finashkin and B.S.Zhits took part in the assembly of the machine and in the tests. The author gives a schematic representation of the loading principle and the electric circuit of the model plant (Fig 1). From it may be seen that

Card 1/2

An Apparatus for the Investigation of the Relaxation
of the Torsion Stress in Metals

SOV/32-24-7-36 '65

a dialbalance was used as dynamometer which made possible a measuring accuracy of up to 0,2%. An extensometer of the usual type was used for the determination of the deformation. A graph of the relaxation curves of carbon steel 20 at 400° is given, with the equation according to which the stress was calculated being given. There are 2 figures and 3 references, which are Soviet.

I.M. Pavlov, and I.P. Radin, Candidates of Technical Sciences.

PURPOSE: This book is intended for metallurgical engineers, research workers
in metallurgy, and may also be of interest to students of advanced courses
in metallurgy.

CONTENTS: This book, consisting of a number of papers, deals with the proper-
ties of heat-resisting metals and alloys. Each of the papers is devoted to
the study of the factors which affect the properties and behavior of metals.
The effects of various elements such as Cr, Ni, and Ti on the heat-resisting
properties of various alloys are studied. The stability and workability
of certain metals as related to the thermal conditions are the object of
another study described. The problems of hydrogen embrittlement, diffusion
and the deposition of certain coatings on metal surfaces by means of
electrophoresis are examined. One paper describes the special methods
used for growing monocrystals of metals. Monocrystal metals are critically
examined and evaluated. Results are given of studies of intermetallic bond-
ing and the behavior of atoms in metal. Tests of turbine and compressor blades are
described. The personalities are mentioned. References accompany most
of the articles.

AUTHOR: Gintsburg, Ya.S.

TITLE: On the third stress relaxation period in metals

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy. Chernaya metallurgiya, no. 9, 1960, 116-119

TEXT: The total deformation in the creep of metals with phase transformations at constant stress ($\sigma_t = \text{const}$) is unlimited and may be expressed by the relation:

$$\epsilon_{\text{total}} = \epsilon_0 + \epsilon_n + \epsilon_B = \epsilon_0 + \epsilon_{\text{creep}} + \epsilon_{\text{phas}} = \text{const}, \quad (2)$$

where $\epsilon_0 \neq \text{const}$, $\epsilon_{\text{creep}} \neq \text{const}$, and $\epsilon_{\text{phas}} \neq \text{const}$,

and the creep presented graphically (Fig1) in three periods of "unlimited" creep with stress relaxation, "invariant" ($B\delta$) stress, and "accumulation".

On the third stress relaxation period ...

All three kinds are observed in real alloys. The two first portions of the relaxation curve had been described for the first time by I.A.Oding (Ref.2), and the third revealed recently (Ref.3) (Ya.S.Ginzburg, "Zavodskaya laboratoriya", XIX, 1953, No.5) and met critically at first (Ref.4-9). This 3rd period is observed with a drastic decrease of volume, as may be seen from relaxation and dilatometric curves (Fig.2) of several chrome-nickel-manganese heat-resistant alloys (The figures in alloy designations mean - the first Cr%, the second Ni%, and the third Mn%; H - niobium, B - tungsten; apart from these, all alloys contained about 1% Mo, 0.8-1.2% V, and 0.1 - 0.2% C). According to the equation (2), the result of the phase transformation $\alpha \rightarrow \beta$ is not an increase but a decrease of the irreversible deformation component, and hence an increase of the reversible (elastic) component, and not a decrease but growth of creep stress $\sigma_t = \epsilon_0 \cdot E_t$, which is plainly contrary to the conceptions of some authors (Ref.4, 5, 6, 8, 9). However up to now, the phenomenon of the 3rd period had been discovered by the author and in most of the Soviet laboratories in tests of heat-resistant alloys only. It is difficult to detect in alloys with faintly developed phase transformations and very small volume of inter-

Card 2/2

On the third stress relaxation period ...

crystalline matters. For instance, the thickness of boundaries visible in a light microscope in heat-resistant alloys in $\alpha - \beta$ transformation was from 5,000 to 40,000 Å or 1,500 - 11,500 interatomic spaces (at the relation of boundary thickness to mean grain thickness 0.001 - 0.008), and in armco iron the grain boundary thickness is only 10 Å, or 4 interatomic spaces. Nevertheless, the phenomenon had been observed in carbon steel "20" and "40" and in armco iron at 550°C, but so faintly that the author did not detect it (Ref.11). A machine has been built at the author's laboratory for relaxation tests of springs (Ref.12) (Ya.S.Ginzburg, "Zavodskaya laboratoriya", XXIV, 1958, No.7), amplifying residual deformation and having a high sensitivity. It made possible the maintaining of deformation of the order of $\pm 5 \cdot 10^{-9}$ mm/mm, compared with only $\pm 1 \cdot 10^{-6}$ mm/mm possible in the best foreign test machines (Ref.13) (W.E.Trumpler, J.appl.Phys., v.12, 1941, No.3). As it can be seen (Fig.3), the 3rd period appeared at 550°C; in (Fig.4) it is also clearly expressed. Its intensity increased with the decreasing carbon content. The observations prove that the 3rd period on the relaxation curve occurs in facilitated boundary creep conditions, and its intensity may depend on temperature as well as the condition of bound-

ary regions (facilitated boundary creep). It is proven that the 3rd period phenomenon exists in heat-resistant as well as in carbon steel and in armco iron, regardless of the nature of the phase transformations. There are 4 figures and 13 references: 11 Soviet-bloc and 2 non-Soviet-bloc.

TITLE: The reversibility of the 3rd stress relaxation period

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy. Chernaya metallurgiya.
no. 11, 1960, 92 - 96

TEXT: As is known, the stress relaxation rate can be decreased for some time in strained connections by means of training or of reloading. The author determined earlier the proper training regime for metals destined for service in temperature below the critical relaxation range (Ref. 1, Ya.S. Gintsburg, Zavodskaya laboratoriya, 1956, No. 2, 223 - 226), and found that in temperatures above this range training and reloading are of little effect (Ref. 2, Ya. S. Gintsburg. Stress relaxation in metals, Mashgiz, 1957). Other authors supposed that reloading may reverse the III length of the relaxation curve. This has been investigated in the subject work on steel in which the III length developed clearly in tests in 650°C (i.e., above the critical relaxation range):

Specimens were preliminarily austenized at 1190°C and cooled in water, and aged at 750° for 4 hours. With the exception of the 18-10-10-2V, steel was nonmagnetic and in the γ -solid solution state; 18-10-10-2V had 20 % ferrite; all specimens had carbides in the structure. Relaxation was tested on

Card 2/5

3/140/60/000/011/009/015
A161/A030

The reversibility of the ...

Relaxation was tested on rings with an equal bending resistance. Reloading was applied in two ways: 1) After a time insufficient for the development of the III relaxation curve length, and 2) After the III length was developed clearly enough. A specimen of 13-0 11-3V steel (Figure 1) was reloaded 2500 hours after the start of the test (when the relaxation curve was yet within the II length, and in full accordance with the irreversible deformation curve, Figure 1b), 4000 hours after the second loading moment and 3500 hours after the start of the test the curve passed into the length III. In the I length range at the first loading the grain of the specimen structure was covered with fine dispersed excess phase segregations (carbides and sigma in different formation stages), with thick lamellar (0.5 - 1.0 micron) carbides and sigma phase on the solid solution gamma grain boundaries, as well as point segregations of sigma which had not completely formed at this stage. In the III range, the number of the fine point segregations in the grain body increased. The sigma formation on the boundaries became more intense and lamellar. Later on (2500 - 5000 hours), the coagulation of sigma continued, and solid segregations were formed in spots on the boundaries (Figure 1). The three other steels were reloaded in the III relaxation range, and the I and II ranges developed

Card 3/8

The reversibility of the

S/148/60/000/011/009/015
A161/A030

again, for a shorter time than at the first loading. The 15-9-8-1.5N steel structure is shown in the drawing made from colour transformation patterns (black - sigma, grey - carbides; light grey background - solid gamma solution; Figure 5). The coagulation continued with the formation of solid sigma films on grain boundaries. In all steels, in the gamma-stage, either completely or with 20% ferrite, the transition of the relaxation curve into the range III was stated to be caused by the formation of spheroids, lamel chains, and solid sigma aggregations on the boundaries. In some steels not included in the subject investigation, the sigma lamella in the range II had serrated edges disappearing in the coagulation processes in transition into the range III turning into planes of facilitated viscous flow (boundary shearing). It is characteristic that the serrations or separate twisted sigma lamella working as thorns present obstacles for viscous boundary shear, and the relaxation rate remains in limits permitting the process of the curve range II. As soon as the coagulation evens out the serrations and "thorns", the relaxation curve passes into the range III, i.e., intense relaxation softening. The diffusion processes leading to coagulation and spheroidization of sigma open the way to dislocations and stress relieving. Recrystallization creates temporary obstacles for dislocations

Card 4/5

The reversibility of the

S/148/60/000/011/009/015
A161/A030

in the form of a "cloud" of dissolved atoms. The "diffusion" of the "cloud" at high temperatures is speedy, and the obstacles disappear. Repeated loading only slightly postpones the moment of the repeated start of range III, and the phenomena in range III are practically irreversible. Microscopic studies were carried out by Candidate of Technical Sciences YE. M. Pivnik. There are 5 figures and 4 Soviet references.

AUTHOR: Ginzburg, Ya. S.

TITLE: Methods of Extrapolating Results of Relaxation Tests

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy, Chernaya metallurgiya, 1961, No. 5, pp 132-138

TEXT: For ensuring reliable long-run operation of bolt and nut joints and springs in steam and gas turbines, it is essential to have available a simple and relatively accurate method of determination of the relaxation stability of materials. The complexity of the task of extrapolating stress relaxation curves increases with increasing operating temperatures reaching phase transformation temperatures in the respective alloys, as a result of which the structure and the properties of high temperature steels and alloys change considerably with time. The author proposes extrapolation of earlier published (Ref. 8: V stank mashinostroyeniya, 1954, No. 3, 40-49) results of long-run tests in the coordinate system σ τ . Long-run relaxation tests of refractory alloys with differing intensities of the phase transformations (intensively ageing ZrO_2 (EI481) and other
Card 1/11

Methods of Extrapolating ...

S/148/61/000/005/008/015
E075/E535

Fe-Cr-Ni-Mn steels with alloying additions of Mo, W, V and Nb, medium ageing - 3043-45 (E1595) and low ageing 3045-15 (E1572, steels) have shown that after the main part of the process has been exhausted and the structure (structural and volume changes) has practically stabilized, the $\sigma-t$ graph shows a stable rectilinear section which is suitable for reliable extrapolation of the results. Fig. 4 shows the main graphs in $\sigma-t$ and in $\sigma-l$ coordinates obtained on the basis of 20 to 30 tests on each of the steels. The time until the section of curves in both systems becomes rectilinear can be determined from the intensity of the phase transformations. For steels which age intensively, the rectilinear section $t_0 - 2'$, representing a relatively uniform speed of decrease in the stress, sets in earlier for the curve in $\sigma-t$ coordinates (plot B) than for the curve in $\ln \sigma-l$ coordinates (plot A). In steels with medium ageing (plots 6 and 7) the rectilinear section is practically the same in both plots. For steels with slow ageing (plots 2 and 5), the section of the curve expressing a uniform speed of decrease in the stress sets in earlier in the semilogarithmic plot. Fig. 1 shows results.

of long-run relaxation tests on ring specimens of the steel EI572 with equal bending strength as proposed by M.A. Oding. The tests were started by the author jointly with A.V. Boyeva and were terminated by Candidate of Technical Sciences L.Ya. Liberman. The test conditions are given in the table. The test temperature (550°C) was below the critical (600°C) so as to prevent appreciable relaxation softening caused by intensification of the processes of coagulation and spheroidization of finely dispersed phases and also to prevent rejection of the σ -phase. The initial stresses σ_0 were chosen so as to obtain relaxation curves of differing configurations and with differing length of the first section of the curve. The plots Fig.1. show the results of the longest investigations: the arrows in the graphs indicate the points of bending of the curves, i.e. the transition from curvilinear to rectilinear sections. Preliminary ageing at 800°C enabled shortening considerably the length of the initial curvilinear section in natural coordinates, the length of which was 1000 hours (curve 2) after ageing at 700°C (curve 1) this time amounted to 13150 hours. Curve 3 did not reach a rectilinear section even after 20200 hours. The duration of the curvilinear Card 3/11

Methods of Extrapolating

²³⁷⁵¹
S/148/61/600/005/008/015
E073/E935

section for the curves 1 and 2 in the system $\sigma - \tau$ is about half that in the system $\sigma - \tau$. Under the loading conditions III the duration of section 1 in the coordinates $\ln \sigma - \tau$ is considerably smaller than for the coordinates $\sigma - \tau$. Thus, for all the investigated loading conditions and stresses the curves pertaining to steel EI572 had a considerably longer curvilinear section in the coordinates $\sigma - \tau$ than in the coordinates $\ln \sigma - \tau$. In the same way as for creep, the presence of a section of a relatively uniform speed of decrease in the stresses enables determining the average relaxation speed for the given section of the curve by means of the formula:

$$v_{rel} = \frac{\sigma_1 - \sigma_2}{\tau_2 - \tau_1} \text{ kg/mm}^2 \cdot \text{hour}$$

The possibility of determining the average relaxation speed enables considering the earlier proposed term of "conventional limit relaxation stress" (see Ref.8) as a real and justified quantity. If the curve has a sufficiently long section with a

Card 4/11

Methods of Extrapolating

¹³⁹⁷⁴
S/148/61/000/005/008/015
EO73/E535

stable uniform speed of decrease of the stress, the extrapolation can be carried out using the average value of the relaxation speed v_{rel} during the given period of time. If the curve does not have a sufficiently long rectilinear section in natural coordinates, the curve has to be drawn in the coordinates $\ln \sigma - \tau$ and the extrapolation carried out on the basis of the exponential law of decreasing stress. In the case of tests of relatively short durations and at relatively high speeds of relaxation, the extrapolation method proposed by I. A. Odintsov (Ref. 5: DAN SSSR, Vol. 71, 1950, No. 5, 883-886) is the only possible and fully satisfactory method. There are 4 figures, 1 table and 11 references: 9 Soviet-bloc and 2 non-Soviet-bloc.

AUTHOR: Gintsburg, Ya.S.

TITLE: Evaluation of the time-to-rupture characteristics of fastening and reinforcing parts of stationary power-generating plant

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy, Chernaya metallurgiya, no. 7, 1962, 181 - 187

TEXT: Bolts and other fastening devices, used in the construction of stationary power plant and operating under conditions of stress relaxation, require periodical tightening-up, which is bound to affect the process of their deformation and fracture. This problem is discussed in the present paper with particular reference to the work of Ye.A. Kheyn (Energomashinostroyeniye, no. 11, 1959) who, in attempting to derive an expression for the time-to-rupture of parts operating at high temperatures under conditions of stress relaxation, made the following assumptions: 1) each re-loading (tightening-up) operation considerably increases the permanent deformation of

Card 1/5

S/148/62/000/007/005/005
E193/E385

Evaluation of

the part; 2) fracture of parts operating under these conditions takes place without entering into the third stage of creep and without localized deformation (necking); 3) fracture takes place after a large number of tightening-up operations, the time intervals between the consecutive operations as well as the initial and final stress levels at each step remaining constant; 4) the process under consideration can be regarded as creep under a changing stress. Using the results of his earlier investigations as well as those obtained by other workers, the present author arrives at several conclusions. A) Periodical re-loading (tightening-up) of bolts causes not an increase but a decrease in the rate of irreversible strain and does not significantly affect its final magnitude. This is demonstrated in Fig. 2, showing the stress relaxation of steel 30572 (E1572) tested at 560 °C under an initial stress of $\sigma_0 = 30 \text{ kg/mm}^2$, which was increased twice (after 675 and after 24 200 hours) to the initial level; the upper curve shows the variation of stress (kg/mm^2 , lefthand scale), the lower curve representing the variation in permanent deformation (ϵ , %, righthand scale).
Card 2/5

Evaluation of

S/148/62/000/007/005/005
E195/E583

For this particular state of experimental conditions the rate of relaxation will continue to decrease up to the fourth tightening-up operation, remaining constant after each subsequent re-loading. B) Although it is true that some creep-resistant alloys (e.g., nimonics) fail in creep without formation of a neck, localized deformation is often observed in high-strength steel creep-test pieces, apart from the fact that the third stage of creep need not be accompanied by the formation of a neck. C) In practice, the time interval between the tightening-up operations is of the order of 10^4 hours and fracture under these conditions cannot be regarded as being caused by creep under a changing stress. D) Work carried out by Kheyn included the determination of "effective stress", i.e. the stress which under conditions of stress relaxation and repeated re-loading should lead to fracture of metal and cause creep at a rate equal to the average creep rate in the time interval under consideration. Since the concept of "effective stress" and the appropriate equations postulated by G. Vidal (Revue de Métallurgie, no. 7, 1956) relate to creep under alternating stress or to fatigue,

Card 3/5

Evaluation of

S/148/62/000/007/005/005
E193/E383

they have no physical meaning when applied to stress relaxation with re-loading operations spaced at intervals of 10^4 hours. E) For all the above reasons an analytical method of determining time-to-rupture of fastening and reinforcing parts of power-generating plant, proposed by Kheyn, cannot be regarded as based on valid physical foundations. There are 4 figures and 4 tables.

3479 NEW MEDIA FOR THE DIFFERENTIATION OF BACTERIA IN ROUTINE EXAMINATION - Neue Differentialnährböden für die laufenden Untersuchungen - Gintscheff P. Z. Sanit.-Epidemiol. Stat. Sofia, Bulgarien - ZBL. BAKT. 1. ABT. ORIG. 1958, 173 1-2 (124-128)

A sensitive indicator changing its colour within narrow margins is described. This indicator was composed from 2 stock solutions, one 2% water blue and the other one 1% phenol red. Both solutions were mixed immediately before the preparation of the media. A lactose medium for the detection of pathogenic enterobacteria contained per l. 20 ml. of the first and 10 ml. of the 2nd solution, while a saccharose-urea medium for differentiation of corynebacteria and a stock solution for fermentation tests each contained 4 ml. of the first and 4 ml. of the 2nd solution per l. The indicator was brown at pH 7.2, red at alkaline and green at acid reaction. On the lactose colour medium *E. coli* produces dark green colonies; other bacteria including the pathogens are greenish, yellow, orange, pink or red. *Proteus* does not swarm. On the corynebacteria medium *C. xerosis* produces a green colour 6 hr. after inoculation. *C. pseudodiphtheriae* is red while *C. diphtheriae* did not produce any change in colour. Olitzki - Rome

Pyridine dyes with negative substituents in the aromatic rings and 1-aryl quaternary salts of pyridine. M. B. Gintseva and I. K. Gintse (Kharkov State Univ.). *Ukrain. Khim. Zhur.* 18, 80-81 (1952) (in Russian). -- In the presence of pyridine, 1-(2,4-dinitrophenyl)pyridinium chloride (I) is cleaved by aromatic amines having neg. groups, with formation of the corresponding dyes, by decompn. of which 1-aryl quaternary pyridine salts are obtained. Heating 2.0 g. I with 2.6 g. p -H₂NC₆H₄CO₂H and 6 ml. abs. EtOH in 2 ml. pyridine 1 hr. on a steam bath gave a ppt. of a red dye, which was washed with Et₂O and H₂O. The pure product (Ib) needles, m. 138° (from MeOH), was identified as $(p$ -HO₂CC₆H₄NHCH₂CH₂CH₂CH₂NH₂CO₂H-p-Cl) (II). absorption max. at 609 mμ in EtOH and 543 mμ in alc. NaOH. The dye forms a red hemiacetate, m. 178°. Decompn. of the dye with alc. HCl gave 1-(p -carboxyphenyl)-pyridinium chloride (III), colorless infusible solid; alkali yields a cheesy pseudobase; the quaternary salt forms double salts with: FeCl₃, green-yellow, decomp. 189°; HgCl₂, decomp. 187-8°; dipicrate, decomp. 157°. Similar reaction of I with anthranilic acid gave the 1,6-(p -HO₂CC₆H₄NH₂) isomer of II crystg. from MeOH in 2 forms: red (violet after drying at 80-70°), m. 133°, and free of Cl, whose compn. was uncertain, and an orange form, m. 140°, which does contain the proper amt. of Cl, and has absorption max. at 523 mμ in EtOH and 545 mμ in alc. NaOH. The dye decompd. with HCl in EtOH to the 1-(p -HO₂CC₆H₄) isomer of III, whose HgCl₂ salt decomp. 170°; FeCl₃ salt, m. 129°; dipicrate, decomp. 155°; the free quaternary salt forms colorless crystals which turn yellow in air. I refluxed 20 min.

with p -H₂NC₆H₄CO₂H in MeOH gave the blue-violet 1,3-(p -HO₂CC₆H₄NH₂) analog of II, m. 30-40°, absorption max. at 515 mμ in EtOH and 588 mμ in alc. NaOH. Decompn. of this with alc. HCl gave after 5-6 hrs. the 1-(p -HO₂CC₆H₄) analog of III which could not be recrystd. after the initial evapn.; a pure specimen, obtained by pptn. with Et₂O from abs. EtOH, m. 203°; picrate, m. 143°. I heated 1 hr. with sulfanilic acid (IV) in EtOH in the presence of

pyridine gave a red-orange dye consisting of a mixt. of the sym. and unsym. products, confirmed by the amt. of I consumed. I (2 g.) heated 30 min. in 10 ml. EtOH with 2.45 g. IV in 3 ml. pyridine and allowed to stand overnight gave 1.63 g. red product with a small admixt. of colorless crystals, indicating, by the amt. of disulfaniline formed, that 25-30% sym. dye was formed. Heating the product with HCl gave a little IV and the filtrate, with picric acid, gave 1-(2,4-dinitrophenyl)pyridinium picrate, m. 147°, whose formation must be ascribed to decompn. of the unsym. dye. The evapd. mother liquor yielded infusible 1-(p -sulfoophenyl)pyridinium salt, which with alkali gave a yellow color. The salt after pptn. from EtOH by Et₂O, is C₁₁H₈NSO₃EtOH.

~~GINTSE, I. K.~~

Cleavage of pyridine 2,4-dinitrochlorophenylate by nitroanilines. N. E. Gligor'eva, I. K. Gintse and M. I. Rozenberg (A. M. Gorki State Univ., Leningrad). *Sbornik Statei Otskheki Khim.* 2, 1448-52 (1953); cl. C.A. 48, 11411af. — Cleavage of pyridine 2,4-dinitrochlorophenylate (I) by $p\text{-O}_2\text{NC}_6\text{H}_4\text{NH}_2$ in EtOH in the presence of pyridine yields 1-(2,4-dinitrophenylamino)-5-(p -nitrophenylamino)-penta-1,3-dien-5-ylidene chloride, violet, m. 140-1° (from EtOH, retaining some EtOH); green, m. 158-60° (from reaction mixt., in AcOH-HCl mixt.). Use of $p\text{-O}_2\text{NC}_6\text{H}_4\text{NH}_2$ in the above reaction gave 1,5-bis(p -nitrophenylamino)-1,3-pentadien-5-ylidene chloride (II), red, m. 142-3°; the use of $m\text{-O}_2\text{NC}_6\text{H}_4\text{NH}_2$ gave the m -nitrophenylamino analog (III), orange, m. 136-7°. Pyridine p -nitrochlorophenylate which does not m. up to 300°, is obtained from I and $p\text{-O}_2\text{NC}_6\text{H}_4\text{NH}_2$ in hot EtOH; it forms a salt with $2\text{H}_2\text{Cl}$, m. 163-4.5° (from H_2O). II heated with MeOH and concd. HCl 0.5 hr. gave $p\text{-O}_2\text{NC}_6\text{H}_4\text{NH}_2$, but III gave pyridine m -chlorophenylate, isolated as salt with H_2Cl , m. 172°; treatment with H_2S gave the free quaternary salt, m. 130°, red powder. Title : Pyridine dyes derivatives of diphenyl

Periodical : Zhur. ob. khim. 24/1, 169-174, Jan 1954

Abstract : The synthesis of three hitherto unknown pyridine dyes : 1,5-bis-(4-amino diphenyl)-pentadiene-1,3-ylidene-5;chloride; 1,5-bis-(4-nitro-4'-aminodiphenyl)-pentadiene-1,3-ylidene-5 chloride and 1,5-bis-(p-aminochlorodiphenylate pyridine)-pentadiene-1,3-ylidene-5 chloride is announced. It is shown that the heating of dyes of benzidine and 4-aminodiphenyl derivatives is followed by an isomeric conversion of the molecule without cleavage of the amine. The derivation of four hitherto unknown quaternary pyridine salts is described. Three references: 1-USSR and 2-German (1904-1952). Table.

GINTSE, I. K.

Reaction products of pyridine 2,4-dinitrochlorophenylate
with diamines. N. E. Gintseva and I. K. Gintse (State
Univ., Kharkov), *Zhur. Obshch. Khim.* 26, 133-4, 1950.
Chem. Abstr. 26, 240-44 (1950) Engl. translation.
Heating 4.2 g. (0.04 mole) $\text{NaC}_6\text{H}_3\text{Cl}_2\text{N}_2$ with 1 g. $p\text{-C}_6\text{H}_4\text{NH}_2$ (II) in EtOH for 10 min. gave a red
ppt. which after washing with H_2O and Me_2CO left behind
76% 4,5-bis(p -phenylenediamino)-1,3-pentadien-5-ylidene
chloride, dark red, m. 147° (contains 0.5 EtOH), for which
a satisfactory crystn. solvent could not be found. Heating
to 128-33° resulted in sublimation of some $p\text{-C}_6\text{H}_4\text{NH}_2$; removal
of the latter with hot Me_2CO gave a brown residue, which
yielded 60% ($p\text{-RC}_6\text{H}_4\text{NH}_2$)Cl (III), yellow (from
 $\text{EtOH-Et}_2\text{O}$), m. 253°, which contained 0.5 mole EtOH ;
picrate, yellow, m. 134° (from EtOH and H_2O). I (1 g.)
and 1.3 g. II HCl salt heated in 5 ml. EtOH and 2 ml. pyri-
dine 15 min. on steam bath gave a red ppt. (initially
violet), which after washing was chromatographed on Al_2O_3 ,
yielding green [$p\text{-}(2,4\text{-NO}_2)_2\text{C}_6\text{H}_3\text{NHCH:CHCH:CHCH:}$ -
 $\text{NH}]_2\text{C}_6\text{H}_4\text{NH:CHCH:CHCH:CHNHHC}_6\text{H}_4(\text{NO}_2)_2$], m. 240°, λ 505 m μ (EtOH), 563 (EtOH-HCl), 660 (HCO_2H).
Refluxed with pyridine 1 hr., filtered and evapd. this gave
some dinitroaniline and III, isolated as the picrate; washing
the residue with H_2O gave an unidentified green product.
Heating I with $p\text{-C}_6\text{H}_4(\text{NHAc})_2$ in EtOH gave 55% ($p\text{-}$
 $\text{NHCH:CHCH:CHCH:NHR}$)Cl (IV, $\text{R} = p\text{-AcNH-C}_6\text{H}_4$), violet, m. 147° (from AcOH), which heated to its
m.p. and treated with H_2O gave ($p\text{-RC}_6\text{H}_4\text{NHAc}$)Cl in
276-7° (from $\text{EtOH-Et}_2\text{O}$); picrate, yellow, m. 180°.
I and $p\text{-Me}_2\text{NC}_6\text{H}_4\text{NH}_2$ gave 57% violet IV ($\text{R} = p\text{-}$
 $\text{Me}_2\text{NC}_6\text{H}_4$), m. 147° (from EtOH), which heated with H_2O

3

1/2

GRIGOR'YAN, N. E. GILLES, T. K.
 gave 63% yellow (δ -RC₆H₄NNMe₂)Cl (V), m. 113° (contains 1 mole EtOH). V as the HCl salt treated with 20% NaOH gave green 1-(δ -dimethylaminocamilo)-1,3-pentadiene-5-ol, decomp. 240°, λ 535 (C₁₄H₁₇, 480 (Me₂CO), 470 (EtOH). I (1 g.) and 1.6 g. III heated 5 min. in EtOH, treated with 1 ml. pyridine and heated until I had reacted (2 hrs.) gave 0.9 g. orange-red solid, which reprecipitated from EtOH with Me₂CO gave pale yellow (δ -C₆H₄NH₂)Cl, m. 285° (from EtOH-Et₂O) (contains 1.25 moles EtOH); picrate, m. 233°. I (23 g.) in EtOH heated with 18 g. α -C₆H₄(NH₂)₂ 0.5 hr. gave 19 g. brown-red IV (R' = α -H₂N-C₆H₄), m. 189-200° (contains 2 moles EtOH); heated to 182° to incipient melting, it gave a brown solid which was passed over Al₂O₃ in EtOH and the effluent soln. treated with Et₂O yielding a brown solid, m. 258°, a compound of 7 moles (α -H₂N-C₆H₄)₂Cl VI) and 1 mole diamine with 2 EtOH. the residual soln. treated with more Et₂O gave yellow needles of VI, m. 78° (contains 0.5 mole EtOH). I (1.2 g.) and 1 g. δ -C₆H₄(NH₂)₂ in EtOH heated 3 min. gave 0.2 g. almost black IV (R' = δ -H₂N-C₆H₄), m. 189°. If the amounts were increased to 1 g. and 1 g. at 100° for 15 min. the product was 0.4 g. of IV. The mixed decomposition of I and III in EtOH at 100° for 15 min. gave a brown solid which was decomposed in EtOH at 100° for 15 min. to give 0.4 g. of the oil which was taken up in EtOH and on cooling the oil was neutralized with NaOH, yielding yellow (δ -RC₆H₄NH₂)Cl, m. 307° (from EtOH), which has 1 NH₂ group available for diazotization. This (0.5 g.) and 0.5 g. I heated in EtOH with 2 ml. pyridine 15 min. and kept 12 hrs. gave 67% red IV (R' = (δ -RC₆H₄)Cl), which does not melt, but decomp. on heating; the product, C₁₄H₁₇N₃Cl₂, contains 3 moles EtOH. Thus unsubstituted diamines can react with quaternary pyridinium salts in 2:1, 1:1, and 1:2 proportions. G. M. Kosolapoff

GINTSE, I. K.

3
 Influence of acids and alkalis on absorption spectra of pyridine dyes. H. E. Grigor'eva, I. K. Gintse, and A. P. Severina (State Univ., Kharkov). *Zh. Obshch. Khim.* 26, 2096-104 (1953); cf. *C.A.* 50, 13778b. — Absorption spectra of several pyridine-base dyes were examd. in 96% EtOH, and in EtOH with varying amts. of HCl, CO₂, or AcOH; some spectra were examd. also in alc. solns. with varying amts. of NaOH. The pyridine dyes in aq. EtOH undergo hydrolysis which is more intense in cases of compds. with lower basicity of the cation; any acid added to the soln. shifts the equil. in the direction of the dye salt, while alkali shifts the equil. in the direction of the base if the dye contains electron-donor groups; with electron-acceptor groups the addn. of alkali yields deeply-colored anionic dyes. The aniline-base pyridine dyes are decolorized in concd. H₂SO₄ owing to salt formation, then reverting to the original dyes on diln. The following abs. max. were noted in EtOH and EtOH with excess HCl, resp., for the following dyes of type RNH(CH₃)₂NH₂Cl (R shown): Ph, 485 mμ, 485 mμ; p-MeC₆H₄, 495, 495; p-MeOC₆H₄, 500, 600; p-HOC₆H₄, 505, 505; p-Me₂NC₆H₄, 500, 550; 1-C₆H₅, 410, 450; 2-C₆H₅, 422, 510; p-EtOC₆H₄, 505, 505; p-HOCC₆H₄, 500, 500; m-O₂NC₆H₄, 500; p-O₂NC₆H₄, 410, 527. The various spectra are reproduced. Treatment of Na enolate of glutaraldehyde (prepd. from excess NaOH and pyridine-SO₂) with p-O₂NC₆H₄NH₂ in EtOH, in the presence of a little HCl gave N-(p-nitrophenyl)-5-(p-nitrophenylimino)-1,3-pentadienylamine-HCl, violet, m. 143-4°, which retains EtOH.

G. M. K.

CHITSE, I K

Products of reaction of β -picollins with 2,4-dinitrochlorobenzene. N. K. Chavtsev, I. K. Glazov, and N. O. Karpuk (State Univ., Kharkov). *Zhur. Obshch. Khim.* 29, 3468-69 (1955). *Ukrainske Zapiski Khim. Gesell. Univ.* 33, 81 (1955). 3-methylpyridine was purified by treatment with CaCl_2 and with a mixt. of phthalic and acetic anhydrides refluxing 6 hrs. The pure material, b. 144° ; picrate, m. 132° . This (2.0 ml.) and 1.6 g. 2,4-dinitrochlorobenzene (I) heated briefly to form a solid, then treated with 20 ml. dry Et_2O and kept 1 day gave 3-methylpyridine 2,4-dinitrophenylate (II), m. 160° , in 45.5% yield. If the components are heated 6 min. at 60° , the same product forms. The salt treated with 15% NaOH gave the red meso-salt of β -methylglutaronaldehyde, m. 101° (from MeOH). Heating the salt with aromatic amines in EtOH at $80-100^\circ$ gave on pptn. with aq. HCl the corresponding 2,4-($\text{ON}_2\text{C}_6\text{H}_3\text{NHAr}$) (Ar as above): Ph, red-brown, m. 148° , λ_{max} 485 m μ ; p-MeOC $_6\text{H}_4$, m. 142° , red-violet, λ_{max} 495; p-BrC $_6\text{H}_4$, blue-violet, m. 139° , λ_{max} 491. In the prepa. of II above there also formed a violet polymethylene dye from the reaction of II with 2 moles 3-methylpyridine; this substance pptd. from MeOH or Me_2CO with Et_2O , was analyzed as $\text{C}_{20}\text{H}_{20}\text{N}_4\text{Cl}_2 \cdot 0.5\text{Me}_2\text{CO}$, m. 157° (from MeOH), or m. 169° (from Me_2CO); this passed over Al_2O_3 gave an upper yellow zone, and lower violet zone. The latter eluted with Me_2CO gave the pure polymethylene (III), contg. 13.7% N and 11.5% Cl, deep violet, m. 130° (heated over P_2O_5 at 70° 1 hr. it gave some I in the sublimate and gave pure $\text{C}_8\text{H}_8\text{N}_2\text{O}_2$, a dark solid). The yellow chromatographic zone, $\text{O}_2\text{N}_2\text{C}_6\text{H}_3$, a dark solid). The yellow chromatographic zone,

TITLE: Monoanils of Glutac~~one~~ Aldehyde (Monoanily glutakonovogo dial'-degida) II. The Influence of the Medium on the Color of the Derivatives of Primary Aromatic Amines (II. Vliyaniye sredi na okras~~ku~~ proizvodnykh pervichnykh aromaticheskikh aminov)

PERIODICAL: Zhurnal obshchey khimii, 1958, Vol. 28, Nr 6, pp. 1682 - 1689 (USSR)

ABSTRACT: The problem concerning the influence of the medium on the color of the organic compounds has interested scientists already since long. The unsalty intraionoc dyes are especially sensitive to changes of the medium. Many hypotheses have already been suggested for this problem (Refs 1-5). That by Kiprianov and his collaborators is widely acknowledged (Ref 6) as are those by other authors (Ref 7) who deal with the dependence of the color change of the intraionoc dyes on the polarity of the solvent. According to this conception the dyes are divided into three types: Some deepen the color with the decrease of the dielectric constant of the solvent (1st type), the others increase it on the same conditions (2nd type), and the rest have an intermediate position (3rd type). The monoanils of glutac~~one~~ aldehyde as derivatives

Card 1/3

Monoanils of Glutacone Aldehyde. II. The Influence of 30479-28-6-55/63
the Medium on the Color of the Derivatives of Primary Aromatic Amines

of the primary aromatic amines are tautomeric compounds the structure of which can be represented by the mentioned formulae of scheme 1. They belong to the intraionic compounds. Each of the mentioned formulae can be represented in form of a dipolar ion. They easily react on changes of the medium by changing their own color in various "neutral" solvents and in the presence of acids and alkali liquors. However, different from the earlier investigated intraionic compounds (Refs 6,7) no fixed dependence of the color change on the polarity of the solvent was noticed. Therefore the authors had to investigate this problem more in detail: The relatively good solubility of the monoanils made it possible to determine their absorption spectra in many organic solvents. Thus eight monoanils of glutacone aldehyde were investigated this way. It was shown that the absorption change of these monoanilines in various solvents is connected with the structure of the complexes of the monoanil as well as with the solvent as such in the case of an equivalent possibility of conversion. Thus some considerations on the causes of the color change of the monoanils of glutacone aldehyde in various solvents, in the presence of acids and alkali liquors are mentioned.

Card 2/3

Monoanils of Glutac~~one~~ Aldehyde. II. The Influence of 304/79-28-6-55/63
the Medium on the Color of the Derivatives of Primary Aromatic Amines

It is shown that there is no principal difference between
solvatochromism and halochromism. There are 4 figures, 3 tables

TITLE:

Pyridine Dyes, Derivatives of the Secondary Amines (Piridinovy-ye krasiteli-proizvodnyye vtorichnykh aminov)

PERIODICAL:

Zhurnal obshchey khimii, 1959, Vol 29, Nr 3, pp 865-869 (USSR)

ABSTRACT:

There are only little data available on these dyes (Refs 1,2). As to color and chemical properties they are considerably differing from the corresponding derivatives of the primary amines. It can be seen from a comparison of the data presented in table 1 that the unsubstituted dye is colored more intensely than the corresponding N-alkyl-substituted dyes and that the substitution of the phenyl radicals for the hydrogens of the amino groups is without any effect on the shift of the absorption maximum. The aniline derivative is readily hydrolyzed; the acid suppresses hydrolysis; in acid solution the extinction coefficient increases by more than two times whereas the absorption intensity of the secondary amine derivatives is hardly changed by the addition of acid. It could be concluded from a comparison of the data given in table 1 that the derivatives of the secondary amines are not hydrolyzable.

Card 1/3

SOV/79-29-3-24/61

Pyridine Dyes, Derivatives of the Secondary Amines

Table 1 illustrates the results of the optical changes of the freshly prepared solutions; on the determination of the variation in the color intensity of the dyes in the time course, in dependence on the concentration, it can be seen that the derivatives of the secondary amines hydrolyze as well, the more rapidly the less the basicity of the cation and the concentration of the dye is. As can further be seen the N-methyl-substituted dye hydrolyzes least, considerably, however, the diphenylamine derivative. These facts show that the hydrolysis of derivatives of the secondary amines is also related to the basicity of the cation the degree of which is determined not only by the nature of the radical but also by its volume. Figures 1 and 2 present the absorption spectra of the dyes of the diphenylamine and methylaniline derivatives in neutral, alkaline and acidified alkaline medium. Figures 3 and 4 give the spectra of the corresponding monoanils of the glutaconic aldehyde. Four N-substituted pyridine dyes and two monoanils of the glutaconic aldehyde were synthesized. Four preparations are new. It is assumed that the peculiarities in the dyeing of the N-alkyl-substituted dyes and their cleavage

TITLE: Products of Hydrogenation of N-phenylpyridinium Chloride. Condensation of N-phenylpiperidinium Hydrochloride With p-Dimethylaminobenzaldehyde

PERIODICAL: Zhurnal obshchey khimii, 1960, Vol 30, Nr 3, pp 1031-1037 (USSR)

ABSTRACT: This is a continuation of previous work (N. Ye. Grigor'yeva, A. B. Organes'yan, I. A. Mysh, ZhOKh, 27, 1565, 1957) on hydrogenation of N-phenylpyridinium chloride (I) over a platinum catalyst under different conditions. The method used was described previously (see above reference). Condensation of N-phenylpiperidinium hydrochloride (II) with p-dimethylaminobenzaldehyde (III) was also studied. It was found that an hydrogenation of (I) over a platinum catalyst, a mixture of N-phenyl- and N-cyclohexylpiperidinium hydrochlorides is formed. The

Card 1/3

Products of Hydrogenation of N-phenylpyridinium
Chloride

SOV/79-30-3-59/69

hexylpiperidinium hydrochlorides is formed. The ratio of the two hydrochlorides in the mixture depends on the conditions of hydrogenation. Condensation of (II) with (III) in acetic anhydride first forms a blue dye. The latter is unstable and on heating decomposes with formation of a red dye. The blue dye was not isolated. Its color is very close to that of Michler's benzhydrol, and it is possible that they are analogs. The red dye is slightly soluble in water, more soluble in alcohol and dichloroethane. It does not crystallize, and has the following absorption maxima: in alcohol 496, in water 504, and in dichloroethane 504 m μ . It is suggested that the red dye is a salt with structure a:

"Investigation of the Dependence of the Immunogenic Activity of Typhoid Vaccine on the Number of Strains Which Enter Into It," L. A. Gintse, Control Inst of Sera and Vaccines imeni L. A. Tarasevich

"Zhur Mikrobiol, Epidemiol, i Immunobiol" No 3, p 79

If strains of typhoid bacteria with a high immunogenic activity are used, one may obtain from a single strain a vaccine which is no less effective than that prepared from several strains. and which may even be superior to the latter in immunogenic activity.

GINTSE, L.A.

Method for obtaining nontoxic antigens. ~~L. A. Gintse, and S. I. Chernyakhovskiy, *Vopr. Med. Biol.* 1954, No. 1, 107-110. (1953); *Kafed. Zhur., Khim.* 1954, No. 1, 107-110.~~ The complete antigen extd. with trichloroacetic acid from the typhoid bacillus was acetylated with Ac_2O for 1.5-24 hrs. This caused the sepn. of the antigen into 2 parts, one pptg. and the other remaining in soln. The N content decreased from 3.5 to 2.8, reducible substances from 45 to 32, and P decreased. The toxicity decreased to $1/10$ and less while retaining good immunogenicity, particularly the part which pptd. Acetylation for 48 hrs. destroyed the toxic as well as the immunizing property of the antigen. Phosphorylation with $POCl_3$ in pyridine did not lower the toxicity. Partial hydrolysis of antigens caused a decrease in the reducible substances from 45 to 34% and phosphate decreased. The toxicity of the prepn. was

greatly lowered thereby, while the immunogenicity was retained at the same level as before. M. Hosen

GINTSE, L.A.

7 Biological and chemical properties of complete antigens, extracted from the media of typhus cultures and subjected to detoxication. L. A. Gintse and V. I. Ivanov. *Zhur. Mikrobiol. Epidemiol. i Immunobiol.* 1953, No. 8, 33-8. -- Immunogenic properties of antigens were assayed by detg. the minimal immunizing dose which, after 2 applications, insured survival of 50% of mice which were infected with lethal doses of typhus culture Ty-4446. Animals were observed for 72 hrs. Complete antigens were prepd. from culture media by pptn. with trichloroacetic acid. Acetylation and partial hydrolysis of the antigens resulted in a 20-fold decrease in its toxicity. Passive and active immunizing activity was decreased by acetylation of the antigens; partial hydrolysis, on the other hand, had little, if any, effect on the immunizing properties of the antigen.

<p>CONGULATING AND CHEMICAL ACTION OF PRECIPITATING BATHS ON THE FORMATION OF VISCOUS FILAMENTS. S. N. Danilov and N. F. Chas. <i>Ind. Chem. Eng. (U. S. S. R.)</i> 5, 720-42 (1936); <i>Ch. C. A.</i> 30, 8325. Study of the physicochem. characteristics of pptg. baths and the coagulating and chem. action on the formation of viscous filaments are studied chiefly by the methods described in the earlier paper. The effect of the chief components of pptg. baths (sulfates of Na, NH₄, Mg and Zn) was studied by comparing the action of baths of various compos. by successive substitution of equiv. amts. of one component for another. In a study of Mg and Zn baths the previous method of volumetric titration could not be used and was replaced by the conversion of unaltered xanthate into insol. Zn xanthate and the analysis of the latter by the Bernhardt method. The same procedure was used for the characterization of Na and NH₄ baths when their action was compared with that of Mg and Zn baths. In their increasing retardation action on the velocity of decompn. of viscous and increasing coagulation power the components can be arranged in the following order: Na₂SO₄, MgSO₄, (NH₄)₂SO₄ and ZnSO₄. The process of decompn. and coagulation of viscous solns. in Mg and Zn baths is accompanied by chem. interaction of viscous with the salts of bivalent metals. The equiv. coeffs. in relation to Na₂SO₄ for the retardation of the decompn. action are: (NH₄)₂SO₄ 1.2, MgSO₄ 1 and ZnSO₄ 4.5-5, and for the coagulation action: (NH₄)₂SO₄ 1.0, MgSO₄ 1.1 and ZnSO₄ 21-2.
